

Chapter 4: Flows on the Circle

To fully describe a differential equation

$$\dot{x} = f(x)$$

one must also define the space the solution curves live on.

Examples:

1. \mathbb{R}^1 - position of a car on a straight track
2. \mathbb{R}^+ - population growth
3. S^1 (unit circle) - motion on circular track, angles.

$\theta = 0, 2\pi$ are two labels for the same point.

$\dot{\theta} = \theta^2$ cannot be vector field on S^1 .

A vector field on S^1 must satisfy $\dot{\theta} = f(\theta + 2n\pi)$ for all $n \in \mathbb{Z}$.

4. S^2 (unit sphere) - motion on earth.

5. $S^1 \times S^1$ (torus) - Two angles.

6. $S^1 \times S^1 \times \mathbb{R}^2$ - Automobile

We will concentrate on the circle.

Example:

$$\dot{\theta} = \omega - a \sin(\theta)$$

→ Phase locking, θ is a phase difference.

Rescale:

$$\tilde{\tau} = \omega t$$

$$\Rightarrow \frac{d\theta}{d\tilde{\tau}} = 1 - \alpha \sin(\theta), \quad \alpha = a/\omega$$

Fixed points:

$$\theta = \sin^{-1}\left(\frac{1}{\alpha}\right) \quad \text{and} \quad \theta = \pi - \sin^{-1}\left(\frac{1}{\alpha}\right)$$

if $|\alpha| \geq 1$, Stability analysis

$$\frac{d\theta}{d\tilde{\tau}} = -\alpha \cos(\theta)$$

$$\Rightarrow \left. \frac{d\theta}{d\tilde{\tau}} \right|_{\sin^{-1}(1/\alpha)} = -\alpha \cos(\sin^{-1}(1/\alpha))$$

$$= -\alpha \sqrt{1 - \alpha^{-2}} \quad (\text{stable})$$

$$\left. \frac{d\theta}{d\tilde{\tau}} \right|_{\pi - \sin^{-1}(1/\alpha)} = -\alpha \cos(\pi - \sin^{-1}(1/\alpha))$$

$$= \alpha \sqrt{1 - \alpha^{-2}} \quad (\text{unstable})$$

locked phase

periodic motion

The period of oscillation can be calculated:

$$T = \int_0^T dt = \int_0^{2\pi} \frac{d\theta}{\dot{\theta}} d\theta = \int_0^{2\pi} \frac{1}{\omega - a \sin \theta} d\theta$$

$$\Rightarrow T = \frac{2\pi}{\sqrt{\omega^2 - a^2}} \quad (\text{If } \omega > a)$$

Why the long period of oscillation?

$a > 1$, and $a \approx 1$.

$\frac{dt}{d\tau} \approx 0 \Rightarrow$ very slow dynamics.

Near $\theta = \pi/2$, $1 - \alpha \sin \theta \approx 1 - \alpha + \alpha (\theta - \pi/2)^2$

$\Rightarrow \frac{dt}{d\tau} \approx 1 - \alpha + \frac{\alpha}{2} \theta^2$

The passage through the slow period can be estimated:

$$T_{\text{passage}} \approx \int_{-\infty}^{\infty} \frac{1}{1 - \alpha + \frac{\alpha}{2} x^2} dx = \frac{\sqrt{2\pi}}{\sqrt{\alpha} \sqrt{1-\alpha}} \approx \frac{\sqrt{2\pi}}{\sqrt{1-\alpha}}$$

This is known as a square root scaling law.

LS

Example:

$$\frac{\hbar C}{2e} \ddot{\phi} + \frac{\hbar}{2eR} \dot{\phi} + I_c \sin \phi = I \quad (\text{superconducting Josephson junction})$$

$[I] = I$ (current)

$\left[\frac{\hbar}{2eR} \right] = \frac{I}{T}$

$\left[\frac{\hbar C}{2e} \right] = \frac{I}{T^2}$

Rescale by $\gamma = \frac{I}{I_c}$

$\frac{1}{T} = \left\langle \frac{\hbar}{2eR} \right\rangle$

$$\Rightarrow \frac{\hbar C}{2eT_{sc}^2} \frac{d^2\phi}{d\gamma^2} + \frac{\hbar}{2eRT_{sc}} \frac{d\phi}{d\gamma} + I_c \sin(\phi) = I$$

Normalizing

$$\frac{\hbar C}{2eT_{sc}^2 I_c} \frac{d^2\phi}{d\gamma^2} + \frac{\hbar}{2eRT_{sc} I_c} \frac{d\phi}{d\gamma} + \sin(\phi) = \frac{I}{I_c}$$

We want

$$\frac{\hbar}{2eRT_{sc} I_c} = \mathcal{O}(1)$$

$$\Rightarrow T_{sc} = \frac{\hbar}{2eRI_c}$$

We obtain the system:

$$\frac{\hbar C}{2e \cdot \hbar^2 I_c} \frac{d^2\phi}{d\gamma^2} + \frac{d\phi}{d\gamma} + \sin(\phi) = \gamma$$

$$\Rightarrow \beta \frac{d^2\phi}{d\gamma^2} + \frac{d\phi}{d\gamma} + \sin(\phi) = \gamma$$

$$\beta = \frac{2eI_c R^2 C}{\hbar}$$

If $\beta \ll 1$ we have the system

$$\frac{d\phi}{d\gamma} + \sin(\phi) = \gamma$$

$$\Rightarrow \frac{d\phi}{d\gamma} = \gamma - \sin(\phi)$$

$\gamma < 1$

$\gamma > 1$

← periodic motion

What is the average velocity?

$$\left\langle \frac{d\phi}{dt} \right\rangle = \frac{1}{T_{per}} \int_0^{T_{per}} \frac{d\phi}{dt} dt = \frac{1}{T_{per}} \cdot 2\pi$$

where

$$T_{\text{per}} = \int_0^{T_{\text{per}}} dt$$

$$= \int_0^{2\pi} \frac{1}{\gamma - \sin(\phi)} dt$$

$$= \frac{2\pi}{\sqrt{\gamma^2 - 1}}$$

$$\Rightarrow \left\langle \frac{d\phi}{dt} \right\rangle = \sqrt{\gamma^2 - 1}, \text{ if } \gamma > 1.$$

Example:

$$\dot{\phi} = \Omega \quad \text{entrainment frequency}$$

$$\dot{\theta} = \omega + A \sin(\phi - \theta)$$

natural frequency

frequency update

Let $\varphi = \phi - \theta$

$$\Rightarrow \dot{\varphi} = \Omega - \omega - A \sin(\varphi)$$

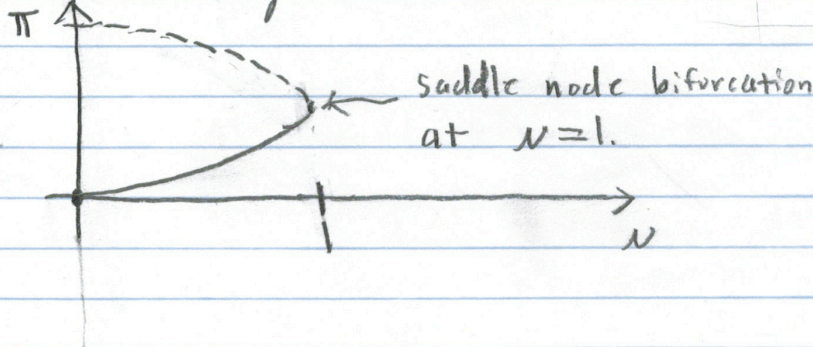

Rescale

$$\tau = A t$$

and let $\nu = \frac{\Omega - \omega}{A}$. This gives the system

$$\frac{d\varphi}{d\tau} = \nu - \sin(\varphi)$$

Bifurcation Diagram

When $0 < \nu < 1$ we get entrainment. The range of entrainment is

$$\omega - A \leq \Omega \leq \omega + A$$

This interval is the range of entrainment.

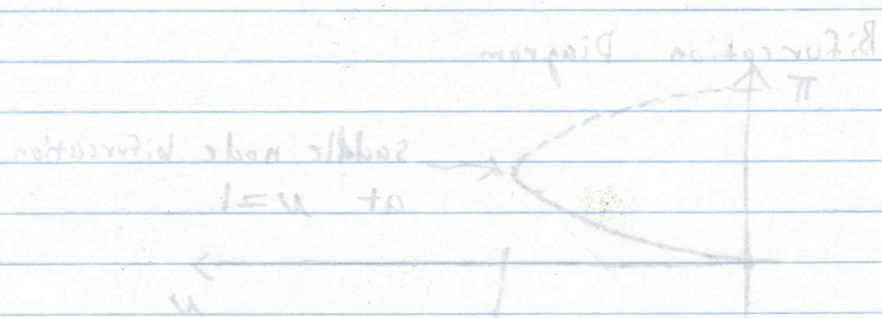

If $\nu > 1$, the period of phase drift is given by:

$$T_{\text{drift}} = \int_0^{T_{\text{drift}}} dt = \int_0^{2\pi} \frac{dt}{d\phi} d\phi = \int_0^{2\pi} \frac{d\phi}{\Omega - \omega - A \sin(\phi)}$$

$$\Rightarrow T_{\text{drift}} = \frac{2\pi}{\sqrt{(\Omega - \omega)^2 - A^2}}$$

Example:
 $\phi = \Omega t$
 $\dot{\phi} = \Omega = \omega + A \sin(\phi)$
Drift frequency
Frequency update

Recall $\Omega = \omega + A \sin(\phi)$
 and let $\nu = \frac{\Omega - \omega}{A}$. This gives the system
 $\dot{\phi} = \nu - \sin(\phi)$

Moving Front

We want to study solutions to the P.D.E.

$$u_x = K u_x u^3 + 1 - u^2$$

We want to find moving fronts.

Move to a coordinate system $z = x - ct$ that moves with the front and to the right.

$$z = x - ct$$

$$\Rightarrow -cu_z = K u_z u^3 + u^2 - 1$$

$$\Rightarrow u_z = \frac{1 - u^2}{c + K u^3}$$

Fixed points occur at $u = \pm 1$. Let's analyze stability:

$$\frac{d u_z}{d z} = \frac{-2u}{c + K u^3} - \frac{(1 - u^2) \cdot 3u^2}{(c + K u^3)^2}$$

$$\Rightarrow \left. \frac{d u_z}{d z} \right|_{\pm} = \mp \frac{2}{c \pm K}$$

If $c > K$ then for $-1 < u < 1$ we have the following phase portrait

The travelling wave looks like:

The acceleration is given by

$$u_{tt} = \frac{d}{dt}(-c u_z) = c^2 u_{zz}$$

Now,

$$c^2 u_{zz} = c^2 \frac{d}{dz} u_z = c^2 \frac{du}{dz} \frac{d}{du} u_z =$$

$$\Rightarrow u_{tt} = c^2 \left(\frac{1-u^2}{Ku^3+c} \right) \left(\frac{-2u}{(c+Ku^3)^2} \right)$$
